WHO CLASSIFICATION OF SKIN TUMOURS Study Guide

WHO classification of skin tumours is an essential framework used by dermatologists, pathologists, and oncologists to categorize and understand the vast array of skin neoplasms. This classification system, developed by the World Health Organization, provides a standardized approach to diagnosing, researching, and managing skin tumors. Accurate classification not only aids in determining prognosis but also guides appropriate treatment strategies. Skin tumors encompass a broad spectrum of benign and malignant lesions, each with distinct histopathological features and clinical behaviors. The WHO classification helps to organize this diversity into structured categories, facilitating clearer communication among healthcare professionals and enhancing patient care.

Overview of the WHO Classification of Skin Tumours

The WHO classification of skin tumours is periodically updated to incorporate new research findings, advances in diagnostic techniques, and emerging tumor entities. The current edition, often referred to as the WHO Classification of Skin Tumours (2018 edition), divides skin tumors into several major groups based on their cellular origin, histopathological characteristics, and biological behavior. These groups include carcinomas, melanocytic tumors, adnexal tumors, soft tissue tumors, and hematolymphoid tumors involving the skin.

The classification emphasizes a comprehensive approach that combines clinical features, histology, immunohistochemistry, and molecular genetics to arrive at an accurate diagnosis. It also recognizes the importance of distinguishing between benign, borderline, and malignant tumors, which has direct implications for patient management.

Major Categories of Skin Tumours in WHO Classification

1. Keratinocyte Carcinomas

Keratinocyte carcinomas are the most common malignant skin tumors, originating from the keratinocytes of the epidermis.

- **Basal Cell Carcinoma (BCC):** The most common skin cancer, characterized by nests of basaloid cells with peripheral palisading. It rarely metastasizes but can cause local destruction.
- **Squamous Cell Carcinoma (SCC):** Arises from keratinocytes of the squamous epithelium.

More aggressive than BCC, with potential to metastasize, especially in immunocompromised individuals.

- **Precursor Lesions:** Includes actinic keratosis and Bowen?s disease, which are considered carcinoma in situ.

2. Melanocytic Tumors

These tumors originate from melanocytes, the pigment-producing cells of the skin.

- **Benign Melanocytic Nevi:** Common moles, usually symmetrical with uniform color and well-defined borders.
- **Melanoma:** Malignant melanoma is a highly aggressive tumor with potential for metastasis. The WHO classifies melanomas based on their histological subtype, including superficial spreading, nodular, lentigo maligna, and acral melanoma.
- **Other Melanocytic Tumors:** Such as Spitz nevus and blue nevus, which can sometimes mimic melanoma.

3. Appendageal (Adnexal) Tumors

These tumors arise from the skin appendages like sweat glands, sebaceous glands, and hair follicles.

- **Eccrine and Apocrine Gland Tumors:** Includes hidradenoma, syringoma, and poroma.
- **Sebaceous Gland Tumors:** Includes sebaceous adenoma and sebaceous carcinoma.
- **Follicular Tumors:** Such as trichoepithelioma and pilomatricoma.

4. Soft Tissue Tumors

These are mesenchymal tumors originating from connective tissues within the skin.

- **Fibrous Tumors:** Such as dermatofibroma and fibrous histiocytoma.
- **Vascular Tumors:** Includes hemangiomas, Kaposi sarcoma, and angiosarcomas.
- **Lipomatous Tumors:** Such as lipomas and atypical lipomatous tumors.

5. Hematolymphoid Tumors

These involve lymphoid and hematopoietic cells infiltrating the skin.

- **Cutaneous Lymphomas:** Including mycosis fungoides and Sézary syndrome.
- **Leukemias:** Such as leukemia cutis.

Histopathological Features and Diagnostic Criteria

Accurate classification relies heavily on histopathological examination, often supplemented by immunohistochemistry and molecular studies.

Key Diagnostic Tools

- **Histology:** Microscopic examination reveals cellular morphology, growth patterns, and stromal interactions.
- **Immunohistochemistry (IHC):** Uses specific markers to distinguish tumor types, such as S100, HMB-45 for melanocytic tumors, or cytokeratins for keratinocyte tumors.
- **Molecular Genetics:** Identifies genetic mutations and chromosomal aberrations, aiding in diagnosis and targeted therapy decisions.

Importance of WHO Classification in Clinical Practice

Correctly classifying skin tumors influences treatment options, prognosis, and follow-up strategies.

Implications for Treatment

- Benign tumors may only require excision or observation.
- Malignant tumors often necessitate wide local excision, sentinel lymph node biopsy, radiotherapy, or systemic therapies.
- Some tumors, like melanoma, require staging and targeted therapy based on molecular findings.

Prognostic Significance

The classification provides prognostic information, with some tumors having a high likelihood of recurrence or metastasis, while others are essentially benign.

Emerging Trends and Future Directions

Advances in molecular pathology continue to refine skin tumor classification, leading to more personalized approaches.

Integration of Molecular Data

New genetic markers are being incorporated into the classification, allowing for better subclassification and targeted treatment options. For example, BRAF mutations in melanoma or MYC amplification in certain cutaneous lymphomas.

Development of Targeted Therapies

Understanding the molecular pathways involved in skin tumors has led to the development of targeted therapies, especially for melanoma and some adnexal tumors.

Conclusion

The WHO classification of skin tumours remains a cornerstone in dermatopathology, providing a comprehensive, standardized framework for diagnosing and managing a wide spectrum of skin neoplasms. As research advances, this classification continues to evolve, integrating new molecular insights to improve patient outcomes. Accurate classification not only enhances diagnostic precision but also facilitates personalized medicine approaches, ensuring patients receive the most effective and targeted treatments available.

This detailed overview underscores the importance of the WHO classification system in the landscape of dermatology and oncology, highlighting its role in advancing understanding, diagnosis, and management of skin tumors.

Who Classification of Skin Tumours: A Comprehensive Guide to Understanding Skin Cancer Types

When discussing skin health, one of the most critical topics is the classification of skin tumours. The who classification of skin tumours serves as a vital framework for clinicians, researchers, and patients to understand the nature, prognosis, and treatment strategies associated with various skin cancers. This structured system helps categorize tumours based on their histopathological features, origins, and biological behaviour, providing clarity in diagnosis and management.

Understanding the Importance of Skin Tumour Classification

Skin tumours encompass a wide spectrum of benign and malignant lesions, each with distinct characteristics. Proper classification influences:

- Diagnosis accuracy
- Treatment planning
- Prognostic assessment

- Research and epidemiological studies

The who classification of skin tumours offers a standardized taxonomy, facilitating uniform communication across medical disciplines and advancing scientific understanding of these lesions.

Foundation of the WHO Classification of Skin Tumours

The World Health Organization (WHO) periodically updates its classification system based on the latest research, integrating histological, immunohistochemical, and molecular data. The 2018 WHO Classification of Skin Tumours is the most recent comprehensive guide, organizing skin tumours into broad categories based on their cellular origin and behaviour.

This classification divides skin tumours primarily into:

- Epithelial tumours
- Melanocytic tumours
- Appendageal (adnexal) tumours
- Soft tissue and other mesenchymal tumours
- Hematolymphoid tumours

Within each category, tumours are further subdivided based on histopathological features.

Main Categories in the WHO Classification of Skin Tumours

- Epithelial Tumours

Epithelial tumours originate from keratinocytes or other epithelial cells of the skin. They include benign, pre-malignant, and malignant lesions.

Benign Epithelial Tumours:

- Seborrheic keratosis
- Verruca (wart)
- Sebaceous hyperplasia

Pre-malignant Epithelial Tumours:

- Actinic keratosis
- Bowen's disease (squamous cell carcinoma in situ)

Malignant Epithelial Tumours:

- Basal cell carcinoma (BCC): The most common skin cancer, arising from basal keratinocytes.
- Squamous cell carcinoma (SCC): Originates from squamous keratinocytes; potential for metastasis.
- Merkel cell carcinoma: A neuroendocrine carcinoma with aggressive behaviour.

- Melanocytic Tumours

These arise from melanocytes, the pigment-producing cells in the skin.

Benign Melanocytic Tumours:

- Melanocytic nevi (moles)
- Spitz nevi

Malignant Melanocytic Tumours:

- Malignant melanoma: The most deadly skin cancer; various subtypes include superficial spreading, nodular, lentigo maligna, and acral lentiginous melanoma.

- Appendageal (Adnexal) Tumours

Originating from skin appendages such as hair follicles, sweat glands, or sebaceous glands.

- Pilomatricoma: Tumour of hair matrix origin.
- Syringoma: Eccrine sweat duct tumour.
- Sebaceous carcinoma: Malignant tumour of sebaceous glands.
- Cylindromas and spiradenomas: Tumours of sweat gland origin.

- Soft Tissue and Mesenchymal Tumours

Includes a variety of benign and malignant tumours derived from connective tissue.

- Dermatofibroma
- Kaposi sarcoma
- Angiosarcoma

- Hematolymphoid Tumours

These are rare but include lymphomas and leukaemias that involve the skin.

- Cutaneous T-cell lymphomas (e.g., mycosis fungoides)
- Other lymphoproliferative disorders

Subclassification of Malignant Skin Tumours

Understanding the subclasses within malignant categories enhances diagnostic precision.

Basal Cell Carcinoma (BCC)

- Nodular BCC
- Superficial BCC
- Morpheaform (sclerosing) BCC
- Pigmented BCC

Features:

- Locally invasive but rarely metastasize
- Often associated with UV exposure

Squamous Cell Carcinoma (SCC)

- Well-differentiated SCC
- Poorly differentiated SCC
- Keratoacanthoma (a variant with rapid growth)

Features:

- Potential to metastasize, especially in immunocompromised patients
- Often arises in sun-exposed areas

Melanoma

- Superficial spreading melanoma
- Lentigo maligna melanoma
- Nodular melanoma
- Acral lentiginous melanoma

Features:

- Highly metastatic potential
- Requires prompt diagnosis and intervention

Molecular and Histopathological Insights

Modern WHO classification also incorporates molecular markers, such as mutations in BRAF, NRAS, and c-KIT genes, especially for melanoma and certain adnexal tumours. Histopathological examination remains the gold standard, with immunohistochemistry aiding in differentiating challenging cases.

Practical Implications of WHO Classification

The classification aids clinicians in:

- Recognizing tumour types based on clinical presentation and histology.
- Determining prognosis ? for example, melanoma subtypes have different survival rates.
- Tailoring treatment strategies, including surgical excision, radiotherapy, or systemic therapies.
- Identifying tumours requiring close follow-up due to metastatic potential.

Conclusion

The who classification of skin tumours provides an essential framework for understanding the vast array of skin neoplasms. By categorizing tumours based on their cellular origin, histological features,

and molecular characteristics, healthcare professionals can improve diagnostic accuracy, inform prognosis, and optimize treatment strategies. As research advances, this classification continues to evolve, integrating new molecular data that promise to refine our understanding of skin tumour biology further. Recognizing the diversity within skin tumours underscores the importance of a multidisciplinary approach to skin cancer management, emphasizing early detection and personalized care.

QuestionAnswer What is the WHO classification of skin tumors based on? The WHO classification of skin tumors is based on histopathological features, cellular origin, and molecular characteristics to provide a standardized framework for diagnosis and management. How many main categories are there in the WHO classification of skin tumors? The WHO classification categorizes skin tumors into several main groups, including keratinocyte tumors, melanocytic tumors, adnexal tumors, and soft tissue tumors, among others. What are the most common keratinocyte tumors classified by WHO? The most common keratinocyte tumors classified by WHO include basal cell carcinoma, squamous cell carcinoma, and their variants. How does the WHO classification differentiate between benign and malignant skin tumors? The classification differentiates based on histopathological criteria such as cellular atypia, invasion depth, mitotic activity, and potential for metastasis. What role does molecular pathology play in the WHO classification of skin tumors? Molecular pathology helps identify genetic mutations and markers that can refine diagnoses, predict behavior, and guide targeted therapies within the WHO classification framework. Are melanocytic tumors classified differently in the WHO system? Yes, melanocytic tumors are classified separately, including benign nevi, dysplastic nevi, and malignant melanoma, with specific subtypes based on histology and molecular features. What is the significance of the WHO classification for dermatopathologists? It provides a standardized nomenclature and diagnostic criteria, improving accuracy, facilitating research, and guiding appropriate treatment strategies. Has the WHO classification of skin tumors been updated recently? Yes, the WHO periodically updates its classifications to incorporate new scientific knowledge, with the latest edition reflecting advancements in molecular and histopathological understanding. How does the WHO classification assist in prognosis and treatment planning? By categorizing tumors based on their histological and molecular features, the classification helps predict tumor behavior and informs clinicians on optimal management approaches. What are some challenging aspects of applying the WHO classification to skin tumors? Challenges include variability in histopathological interpretation, overlapping features among tumor types, and the need for molecular testing, which may not be universally available.

WHO CLASSIFICATION OF TUMOURS OF THE LUNG PLEURA

WHO classification of tumours of the lung pleura

The World Health Organization (WHO) classification of tumours of the lung and pleura provides a comprehensive framework for diagnosing, categorizing, and understanding the diverse neoplasms that originate in these regions. This classification is pivotal for clinicians, pathologists, and researchers because it standardizes terminology, facilitates accurate diagnosis, guides treatment strategies, and aids in prognostication. This article delves into the detailed WHO classification of lung and pleural tumours, exploring the various tumour types, their histopathological features, clinical relevance, and updates from the latest WHO editions.

Overview of WHO Classification of Lung and Pleural Tumours

The WHO classification system for lung and pleural tumours was first established to address the heterogeneity of neoplasms arising within these thoracic structures. It is periodically updated to incorporate advances in pathology, molecular biology, and clinical insights. The latest WHO classification categorizes tumours into benign, borderline, and malignant entities, based on histological features, behaviour, and molecular characteristics.

The classification encompasses tumours originating from:

- Lung parenchyma (primarily epithelial tumours)
- Pleura (mesothelial tumours)
- Other rare tumours of the lung and pleura

Understanding these categories is essential for accurate diagnosis and appropriate management.

Classification of Tumours of the Lung

Lung tumours are predominantly epithelial in origin, with non-small cell lung carcinomas (NSCLCs) being the most common, followed by small cell lung carcinomas (SCLCs). The WHO classification emphasizes histological subtypes, molecular alterations, and clinical implications.

Benign Lung Tumours

Benign lung tumours are rare and usually asymptomatic. They are often discovered incidentally during imaging studies. Main benign tumours include:

- Bronchial adenomas (now termed neuroendocrine tumors of low malignant potential)
- Hamartomas
- Leiomyomas
- Hemangiomas

Malignant Lung Tumours

Malignant tumours are classified primarily based on histological features into non-small cell lung carcinomas and small cell lung carcinomas.

Non-Small Cell Lung Carcinomas (NSCLCs)

This group includes the most prevalent lung cancers and is subdivided into:

- adenocarcinoma
- squamous cell carcinoma
- large cell carcinoma

Adenocarcinoma: The most common type, especially among non-smokers. It originates from glandular epithelium and often occurs peripherally.

Squamous cell carcinoma: Typically arises centrally within the bronchi and is strongly associated with smoking.

Large cell carcinoma: A diagnosis of exclusion characterized by undifferentiated malignant cells without glandular or squamous differentiation.

Small Cell Lung Carcinoma (SCLC)

SCLC accounts for approximately 15% of lung cancers. It is characterized by small, round to oval cells with neuroendocrine features, high mitotic rate, and aggressive behavior. It often presents with extensive disease at diagnosis and responds initially to chemotherapy and radiotherapy.

Other Rare Lung Tumours

The WHO also recognizes rare tumours such as carcinoid tumours, sarcomatoid carcinomas, and lymphomas involving the lung.

Classification of Tumours of the Pleura

Pleural tumours primarily originate from mesothelial cells lining the pleura. The WHO classification emphasizes mesothelial tumours, their benign, borderline, and malignant categories.

Benign Pleural Tumours

The most common benign pleural tumour is:

- Localized fibrous tumour of the pleura (also called solitary fibrous tumour)

These are usually asymptomatic, slow-growing, and incidentally found.

Borderline and Intermediate Tumours

This category includes tumours with uncertain malignant potential, though they are less well-defined compared to malignant tumours.

Diffuse Mesothelioma of the Pleura

While classified as malignant, mesotheliomas are a distinct entity with unique pathological features.

Malignant Pleural Tumours

The most significant malignant pleural tumour is:

- Malignant mesothelioma

This tumour arises from mesothelial cells and is strongly associated with asbestos exposure.

WHO Classification of Mesothelial Tumours

Mesothelial tumours are categorized based on histological subtypes, differentiation, and cellular features:

- Epithelioid mesothelioma: The most common form, characterized by epithelial-like cells.

- Sarcomatoid mesothelioma: Composed of spindle-shaped cells resembling sarcomas.

- Biphasic (mixed) mesothelioma: Contains both epithelioid and sarcomatoid components.

Additional features include the grading of cellular atypia, mitotic activity, and invasion patterns, which influence prognosis.

Key Features and Diagnostic Criteria in WHO Classification

The WHO classification emphasizes several diagnostic criteria:

- Histopathological features: Cell morphology, growth patterns, invasion depth.

- Immunohistochemistry: Markers such as calretinin, WT-1, cytokeratin 5/6 for mesothelial origin; TTF-1, Napsin A for adenocarcinomas; p40, p63 for squamous cell carcinomas.

- Molecular features: Genetic alterations, e.g., EGFR mutations in adenocarcinoma, BRAF, KRAS mutations, and PD-L1 expression relevant for targeted therapy.

Importance of WHO Classification in Clinical Practice

The WHO classification guides clinicians by:

- Providing a standardized terminology for diagnosis and communication.

- Informing prognosis; for example, adenocarcinomas generally have better outcomes compared to small cell carcinomas.

- Influencing treatment decisions; targeted therapies depend on molecular subtypes.

- Facilitating research and epidemiological studies through consistent categorization.

Updates in the Latest WHO Classifications

The WHO periodically revises its classification to incorporate advances in pathology and molecular biology. Notable updates include:

- Recognition of new subtypes of lung adenocarcinoma (e.g., lepidic, acinar, papillary).

- Inclusion of molecular markers as diagnostic criteria.

- Clarification of borderline and pre-invasive lesions.

- Better characterization of mesothelial tumours, including epithelioid, sarcomatoid, and biphasic variants.

Conclusion

The WHO classification of tumours of the lung and pleura remains a cornerstone in thoracic pathology, fostering precise diagnosis, guiding treatment, and improving understanding of tumour biology. Its systematic approach to categorizing benign, borderline, and malignant neoplasms based on histological, immunohistochemical, and molecular features ensures consistency across institutions and enhances patient care. Staying updated with WHO revisions is essential for healthcare professionals involved in the management of thoracic tumours, ultimately leading to better outcomes for patients.

WHO Classification of Tumours of the Lung Pleura

The World Health Organization (WHO) classification of tumours of the lung and pleura represents a comprehensive framework that guides pathologists, oncologists, and researchers in diagnosing, categorizing, and managing thoracic neoplasms. This classification system, regularly updated to incorporate advances in molecular pathology and histopathology, provides a standardized language that enhances clinical decision-making and facilitates epidemiological studies. In this review, we explore the detailed taxonomy of pleural tumours as outlined by the WHO, emphasizing their histopathological features, molecular characteristics, and clinical implications.

Introduction

The pleura, a vital serous membrane enveloping the lungs and lining the thoracic cavity, is a site for a diverse array of benign and malignant tumours. Malignant pleural mesothelioma (MPM) is the most notorious primary neoplasm arising from the mesothelial cells, but secondary tumours such as

metastases from lung, breast, and other carcinomas also involve the pleura. The WHO classification provides a structured approach to distinguish these entities, primarily focusing on mesothelial neoplasms, fibrous tumours, and other rare variants.

Understanding the WHO classification is essential for accurate diagnosis, prognostication, and therapeutic planning, especially given the heterogeneity of pleural tumours and the evolving landscape of molecular diagnostics.

Primary Tumours of the Pleura

Primary tumours originate from the mesothelial lining or associated stromal components. They are classified based on histopathological features, immunohistochemical profiles, and molecular alterations.

Mesothelial Tumours

Mesothelial neoplasms are the most common primary pleural tumours and encompass benign, borderline, and malignant categories.

Benign Mesothelial Tumours

- Localized Mesothelial Hyperplasia: Reactive proliferation of mesothelial cells often associated with inflammation or trauma.
- Well-Differentiated Papillary Mesothelial Tumour (WDPMT): A rare benign entity characterized by papillary proliferation of mesothelial cells with minimal atypia and no invasion.

Malignant Mesothelial Tumours

- Malignant Mesothelioma (MM): The most significant primary malignant tumour of the pleura, with distinct histological subtypes and molecular features.

Malignant Mesothelioma Subtypes

The WHO recognizes three main histological subtypes, each with differing prognosis and therapeutic responses:

- Epithelioid Mesothelioma
- Sarcomatoid Mesothelioma

- Biphasic (Mixed) Mesothelioma

Epithelioid Mesothelioma:

Most common (~60-70%), characterized by polygonal cells forming tubules, papillae, or solid sheets. Frequently exhibits a prominent fibrous stroma and tends to have a better prognosis.

Sarcomatoid Mesothelioma:

Less common (~10-20%), composed of spindle-shaped cells resembling sarcoma. These tumours are often more aggressive and less responsive to therapy.

Biphasic Mesothelioma:

Contains both epithelioid and sarcomatoid components, with prognosis depending on the proportion of each.

Molecular and Immunohistochemical Features of Mesothelioma

- Key Immunohistochemical Markers:

- Positive: Calretinin, WT1, D2-40 (podoplanin), Cytokeratin 5/6, Mesothelin
- Negative: Carcinoma markers such as TTF-1, CEA, Ber-EP4

- Molecular Alterations:

- Loss of BAP1 expression
- CDKN2A (p16) deletion detectable via FISH
- Rare mutations in BRAF, NRAS

Other Mesothelial Tumours

- Localized Malignant Mesothelioma: Rare, similar to diffuse but confined to localized areas.
- Multicystic Mesothelioma: Generally benign, presenting as multicystic lesions.

Fibrous and Other Tumours of the Pleura

Aside from mesothelial origins, the pleura can host fibrous and miscellaneous tumours.

Solitary Fibrous Tumour (SFT)

- Originates from fibroblastic mesenchymal cells.
- Usually benign but can be malignant.
- Features: Well-circumscribed, spindle cells with high vascularity, "patternless" pattern, and CD34 positivity.
- Malignant SFTs show increased cellularity, atypia, mitoses, necrosis.
- Molecular hallmark: NAB2-STAT6 gene fusion detectable via immunohistochemistry (STAT6 nuclear positivity).

Fibrosarcoma and Other Sarcomas

Rare; includes fibrosarcoma, malignant peripheral nerve sheath tumour, and angiosarcoma. These are generally distinguished through histomorphology and immunoprofile.

Mesenchymal Tumours with Other Differentiations

- Lipomas and Liposarcomas
- Hemangiopericytoma

Secondary Tumours of the Pleura

Metastatic involvement of the pleura is common, especially from lung, breast, and other carcinomas.

Common Metastases

- Lung Carcinomas: Adenocarcinoma, squamous cell carcinoma
- Breast Carcinoma
- Gastrointestinal Tumours
- Lymphomas and Leukemias

Immunohistochemistry and molecular studies help determine the primary site, especially in poorly differentiated tumours.

Rare and Unusual Pleural Tumours

- Mesenchymal chondrosarcoma
- Malignant fibrous histiocytoma
- Synovial sarcoma

These are exceedingly rare but are recognized within the WHO framework based on histopathology and molecular features.

Diagnostic Challenges and Advances

Accurate classification relies on a combination of histopathology, immunohistochemistry, and increasingly, molecular diagnostics.

Role of Molecular Diagnostics

- Detection of BAP1 loss and CDKN2A deletions for mesothelioma
- Identification of NAB2-STAT6 fusion in SFT
- Next-generation sequencing panels for rare entities

Diagnostic Algorithms

- Use of panel immunohistochemistry to differentiate mesothelioma from metastatic carcinoma
- Employing molecular markers for ambiguous cases

Clinical Implications of WHO Classification

The WHO classification informs prognosis and guides management strategies:

- Benign vs. Malignant: Surgery for benign tumours; multimodal therapy for mesothelioma.
- Histological Subtypes: Epithelioid mesotheliomas have better outcomes.
- Molecular Features: Potential targets for novel therapies.

Conclusion

The WHO classification of tumours of the lung and pleura offers a detailed and nuanced taxonomy that reflects advances in our understanding of thoracic neoplasms. It emphasizes the importance of integrating histopathological, immunohistochemical, and molecular data to achieve accurate diagnosis. As research continues to evolve, especially in molecular genetics and targeted therapies, this classification will likely undergo further refinements, ultimately improving patient outcomes

through tailored treatment approaches.

Understanding the diverse spectrum of pleural tumours aids clinicians and pathologists in making precise diagnoses, prognostic assessments, and guiding appropriate management. The ongoing evolution of the WHO classification underscores the importance of multidisciplinary collaboration in thoracic oncology.

QuestionAnswer What is the WHO classification of tumors of the lung and pleura? The WHO classification of tumors of the lung and pleura is a standardized system that categorizes benign and malignant tumors based on histological features, genetic profiles, and clinical behavior to guide diagnosis and treatment. How are mesotheliomas classified in the WHO system? In the WHO classification, mesotheliomas are categorized into epithelioid, sarcomatoid, biphasic (mixed), and rare variants, based on their cellular morphology and immunohistochemical profiles. What are the main types of primary lung carcinomas according to WHO? The main types include non-small cell lung carcinomas (adenocarcinoma, squamous cell carcinoma, large cell carcinoma) and small cell lung carcinoma, each with distinct histological and molecular features. How does the WHO classify benign tumors of the lung and pleura? Benign tumors are classified as hamartomas, papillomas, lipomas, and other rare benign neoplasms, characterized by their benign histological appearance and non-invasive behavior. What is the significance of the WHO classification in clinical management? The WHO classification helps in accurate diagnosis, prognosis, and selection of appropriate treatment strategies by providing a standardized framework for tumor categorization. Are genetic features incorporated into the WHO classification of lung and pleural tumors? Yes, the WHO classification increasingly incorporates molecular and genetic markers that aid in subclassification, prognosis, and targeted therapy options. How are metastatic tumors to the lung and pleura classified in the WHO system? Metastatic tumors are classified based on their primary origin and histological similarity, with common types including metastases from breast, colon, and other cancers, but they are not part of the primary WHO tumor classification. What updates have recent WHO classifications introduced for lung and pleural tumors? Recent updates include enhanced molecular characterization, recognition of new tumor variants, and refined criteria for differentiating benign from malignant lesions to improve diagnostic accuracy. How does the WHO classification address rare tumors of the lung and pleura? The WHO classification provides specific categories for rare tumors such as solitary fibrous tumors, carcinoids, and other uncommon neoplasms, facilitating their recognition and management. Why is the WHO classification important for pathologists and clinicians? It ensures consistent diagnosis, informs prognosis, guides treatment decisions, and fosters research by providing a comprehensive, evidence-based framework for tumor categorization.
