Sample AQA A2 Chemistry Questions and Answers

Below are representative questions across different topics accompanied by detailed answers.

Organic Chemistry

Question 1:

Describe the mechanism of the nucleophilic addition of cyanide ion to an aldehyde. Include the key steps and electron movement.

Answer:

The nucleophilic addition of cyanide (CN^-) to an aldehyde proceeds via the following steps:

- Nucleophilic Attack:

The lone pair of electrons on the cyanide ion attacks the electrophilic carbon atom of the aldehyde's carbonyl group. This occurs because the carbon of the carbonyl is partially positive due to the electronegativity difference between carbon and oxygen.

- Formation of Tetrahedral Intermediate:

The attack results in a tetrahedral intermediate where the carbon now bears a negative charge on the oxygen atom.

- Protonation:

The oxygen atom picks up a proton (H^+) from the surrounding solvent (usually water or acid),

forming a hydroxyl group.

- Product Formation:

The overall result is a hydroxynitrile (cyanohydrin), with the structure $R^?CH(OH)^?CN$.

Electron Movement:

- The lone pair on $CN^?$ attacks the carbon of the carbonyl, forming a bond.
- The pi bond electrons in the $C=O$ shift onto oxygen, creating a negative charge.
- Protonation of oxygen stabilizes the intermediate.

Inorganic Chemistry

Question 2:

Explain the trend in atomic radius across a period in the periodic table. How does this trend influence the chemical reactivity of elements?

Answer:

Trend Explanation:

- As you move across a period from left to right, the atomic radius decreases.
- This occurs because additional protons in the nucleus increase the nuclear charge, pulling electrons closer to the nucleus.
- Although electrons are added to the same energy level, the increased positive charge results in a stronger attraction, reducing the size of the atom.

Impact on Chemical Reactivity:

- Elements on the left of the period (metals) tend to have larger atomic radii and are more likely to lose electrons, making them more reactive metals.
- Elements on the right (non-metals) have smaller atomic radii and a higher tendency to gain electrons, making them more reactive non-metals.
- The decreasing atomic radius enhances the effective nuclear charge experienced by valence electrons, influencing how readily an element participates in chemical reactions.

Physical Chemistry

Question 3:

Calculate the standard enthalpy change for the combustion of ethanol ($\text{C}_2\text{H}_5\text{OH}$) given the following data:

Reaction	ΔH (kJ/mol)
----- -----	
$\text{C}_2\text{H}_5\text{OH} + 3\text{O}_2 \rightarrow 2\text{CO}_2 + 3\text{H}_2\text{O}$	-1367
$\text{C}_2\text{H}_6 + 3.5\text{O}_2 \rightarrow 2\text{CO}_2 + 3\text{H}_2\text{O}$	-1560
$\text{C}_2\text{H}_4 + 1.5\text{O}_2 \rightarrow 2\text{CO} + 2\text{H}_2\text{O}$	-1411

Note: Use Hess's Law to find ΔH for the combustion of ethanol.

Answer:

Step 1: Recognize that the combustion of ethanol can be related to the combustion of ethane and ethene, but more straightforwardly, the data provided suggest using Hess's Law by constructing a suitable cycle.

Alternatively, if only the above data are provided, and assuming the data are for combustion reactions, the most accurate approach is to use the standard enthalpy of formation method. However, since the data are for combustion, the most effective way is to use known combustion reactions directly if available.

Given the data, the common approach is:

- Recognize the combustion of ethanol is:

- The ΔH for this reaction is given as -1367 kJ/mol.

Therefore, the standard enthalpy change for the combustion of ethanol is -1367 kJ/mol.

Analyzing Typical AQA A2 Chemistry Questions and Their Answers

To illustrate the nature and depth of AQA A2 Chemistry exam questions, we analyze representative examples across different topics, providing insights into effective answering strategies.

Example 1: Calculations in Acid-Base Chemistry

Question:

A 25.0 cm³ sample of hydrochloric acid reacts completely with 0.015 mol of sodium hydroxide. Calculate the concentration of the hydrochloric acid solution.

Answer Breakdown:

- Identify knowns:

Volume of HCl = 25.0 cm³ = 0.0250 dm³

Moles of NaOH = 0.015 mol

- Reaction equation:

HCl + NaOH → NaCl + H₂O

- Mole ratio:

1 mol HCl reacts with 1 mol NaOH

- Calculate concentration of HCl:

$$\text{Concentration (mol/dm}^3\text{)} = \text{moles} / \text{volume (dm}^3\text{)}$$

$$= 0.015 \text{ mol} / 0.0250 \text{ dm}^3$$

$$= 0.6 \text{ mol/dm}^3$$

Key Points:

- Recognize the mole ratio from the balanced equation.
- Convert units consistently.
- Use the formula for concentration directly.

Strategy:

Always identify the reaction type, write a balanced equation, and apply molar relationships.

Example 2: Understanding Equilibrium and Le Châtelier's Principle

Question:

The equilibrium:

is established in a container at constant temperature. Explain what would happen to the equilibrium position if:

- The pressure is increased
- The temperature is increased

Answer:

- Increase in pressure:

According to Le Châtelier's principle, increasing pressure favors the side with fewer moles of gas.

- Reactants: $1 \text{ N}_2 + 3 \text{ H}_2 = 4 \text{ moles}$
- Products: $2 \text{ NH}_3 = 2 \text{ moles}$
- Result: The equilibrium shifts to the right, producing more ammonia.

b) Increase in temperature:

The reaction is exothermic in the forward direction.

- Increasing temperature shifts the equilibrium to absorb heat, favoring the endothermic reverse reaction.
- Result: The equilibrium shifts to the left, decreasing ammonia production.

Key Points:

- Recognize the effect of pressure based on molar quantities.
- Understand exothermic/endothermic nature to interpret temperature effects.

Strategy:

Use Le Châtelier's principle systematically, considering how each change affects the equilibrium position.

Example 3: Organic Mechanisms and Reaction Pathways

Question:

Describe the mechanism for the nucleophilic substitution of bromoethane with hydroxide ions, including any important intermediate steps.

Answer:

- Step 1: Initiation of nucleophilic attack

The hydroxide ion (OH^-) acts as a nucleophile, attacking the electrophilic carbon atom bonded to bromine in bromoethane ($\text{C}_2\text{H}_5\text{Br}$).

- Step 2: Transition state formation

A pentavalent transition state forms as the nucleophile approaches.

- Step 3: Departure of leaving group

The bromide ion (Br^-) leaves, resulting in the formation of ethanol ($\text{C}_2\text{H}_5\text{OH}$).

- Overall reaction:

Key Points:

- This is an $\text{S}_\text{N}2$ mechanism, characterized by a one-step process.
- The nucleophile attacks as the leaving group departs simultaneously.

Strategy:

Draw mechanism arrows clearly, identify the nucleophile, leaving group, and the transition state.
