Introduction to Signals and Systems

Signals and systems form the backbone of modern technology, from telecommunications to multimedia processing.

What Are Signals?

Signals are functions that convey information about the behavior or attributes of some phenomenon. They can be classified based on various criteria:

- Continuous-time signals: Defined for every value of time (e.g., analog audio signals).
- Discrete-time signals: Defined only at discrete time intervals (e.g., digital samples).
- Analog signals: Infinite resolution and continuous in time and amplitude.
- Digital signals: Discrete in both time and amplitude, suitable for digital processing.

What Are Systems?

Systems are entities that process input signals to produce output signals. They can be characterized by:

- Linearity: The system's response to a sum of inputs equals the sum of the responses.
- Time-invariance: The system's characteristics do not change over time.
- Causality: The output at any time depends only on present and past inputs.

- Stability: Bounded inputs produce bounded outputs.

Fundamental Concepts in Signals and Systems

Oppenheim and Willsky emphasize understanding the mathematical underpinnings of signals and systems, including their classification, properties, and analysis tools.

Mathematical Representation of Signals

Signals are represented as functions, often expressed mathematically as:

- $x(t)$ for continuous-time signals.
- $x[n]$ for discrete-time signals.

System Properties and Classifications

Key properties used to analyze systems include:

- Linearity: $T\{ax_1 + bx_2\} = aT\{x_1\} + bT\{x_2\}$
- Time-Invariance: $T\{x(t - t_0)\} = y(t - t_0)$
- Causality: Output depends only on current and past inputs.
- Memory: Whether the system's output depends on past inputs.
- Stability: BIBO (Bounded Input, Bounded Output) stability criterion.
