Sample Verilog Multiple Choice Questions with Answers

Below, we explore a curated set of MCQs, explaining each question?s intent and providing detailed answers. These questions are representative of what learners might encounter in exams or practical assessments.

1. Which of the following best describes a 'module' in Verilog?

A) A block of code used for generating test signals

B) The fundamental building block used to model hardware components

C) A syntax error that occurs during compilation

D) A special type of variable used for storing data

Answer: B) The fundamental building block used to model hardware components

Explanation:

In Verilog, a module is a core construct representing a hardware component or system. It encapsulates a piece of hardware design, including inputs, outputs, internal logic, and submodules. Modules are hierarchical, enabling complex designs to be built from simpler submodules. Unlike options A, C, and D, which are either incorrect or unrelated, the correct answer emphasizes the modular and hierarchical nature of Verilog design.

2. What is the primary purpose of the 'always' block in Verilog?

A) To define combinational logic that executes once during simulation

B) To specify sequential logic that executes repeatedly based on a sensitivity list

C) To declare variables that retain their value across simulation cycles

D) To initialize variables at the start of simulation only

Answer: B) To specify sequential logic that executes repeatedly based on a sensitivity list

Explanation:

The 'always' block in Verilog is used to describe both combinational and sequential logic, depending on how it is written. When used with a sensitivity list (e.g., `always @(posedge clk)`), it models sequential logic that triggers on clock edges. Without a sensitivity list, it can model combinational logic. The key aspect here is its role in describing logic that executes repeatedly based on specific signals, making option B the best choice.

3. Which data type is used to declare a 4-bit register in Verilog?

A) reg [3:0] my_reg;

B) wire [3:0] my_wire;

C) bit [4] my_bit;

D) reg my_reg[3:0];

Answer: A) reg [3:0] my_reg;

Explanation:

To declare a 4-bit register, Verilog uses the `reg` keyword with a range specifying the bit width. The syntax `reg [3:0] my_reg;` creates a 4-bit register, with bits numbered from 3 down to 0. Option B declares a wire, which is used for combinational signals, not registers. Option C uses an incorrect data type `bit`, which is not standard in Verilog-2001. Option D suggests an array of regs, which is not the typical way to declare a 4-bit register.

4. In Verilog, what does the 'assign' statement do?

A) Declares a new variable

B) Describes combinational logic by assigning values continuously

C) Initiates sequential logic triggered on clock edges

D) Instantiates a module

Answer: B) Describes combinational logic by assigning values continuously

Explanation:

The 'assign' statement in Verilog is used for continuous assignment, which models combinational logic. It updates the assigned signal immediately whenever the right-hand side expression changes. This is different from procedural assignments within 'always' blocks, which are triggered by events. Options A, C, and D do not accurately describe the function of 'assign'.

5. Which of the following is NOT a valid Verilog keyword?

A) module

B) always

C) process

D) reg

Answer: C) process

Explanation:

In Verilog, `module`, `always`, and `reg` are all valid keywords used for defining modules,

behavior, and data types, respectively. However, `process` is not a Verilog keyword; it is more common in VHDL. Recognizing valid keywords is crucial for correct syntax and avoiding compilation errors.
