Question What is the primary pigment involved in photosynthesis in Campbell Biology? The primary pigment involved in photosynthesis is chlorophyll, specifically chlorophyll a. Which part of the chloroplast is responsible for the light-dependent reactions? The thylakoid membranes of the chloroplast are responsible for the light-dependent reactions. What are the main products of the Calvin cycle? The main products of the Calvin cycle are glyceraldehyde-3-phosphate (G3P), which can be used to form glucose and other carbohydrates. How does the absorption spectrum of chlorophyll relate to photosynthesis efficiency? Chlorophyll absorbs light most efficiently in the blue and red wavelengths, which enhances the overall efficiency of photosynthesis. What role do accessory pigments play in photosynthesis? Accessory pigments, such as carotenoids, broaden the range of light wavelengths a plant can use by capturing additional light energy and transferring it to chlorophyll a. During photosynthesis, what is the source of the oxygen released into the atmosphere? The oxygen released during photosynthesis comes from the splitting of water molecules during the light-dependent reactions. What are the main differences between photosystem I and photosystem II? Photosystem II absorbs light best at 680 nm and is involved in water splitting, while Photosystem I absorbs light best at 700 nm and is involved in producing NADPH; they work sequentially in the light-dependent reactions. How does photorespiration affect photosynthesis in C3 plants? Photorespiration occurs when the enzyme Rubisco fixes oxygen instead of carbon dioxide, leading to a loss of fixed carbon and decreased photosynthetic efficiency in C3 plants, especially under high oxygen or high temperature conditions. What is the significance of the proton gradient in ATP synthesis during photosynthesis? The proton gradient generated across the thylakoid membrane drives ATP synthase to produce ATP, which provides energy for the Calvin cycle. How do environmental factors like light intensity and carbon dioxide concentration affect the rate of photosynthesis? Increased light intensity and higher carbon dioxide concentration generally enhance the rate of photosynthesis until other factors become limiting, such as enzyme activity or temperature.
